

Hardening the front door — fuzz the param validator v0.99.19

Every route parses user query params through registry.qstr/qint/qflag. Contract: bad input → 400, NEVER a 500. Proved it holds under 878k adversarial cases.

THE GUARANTEE

RESULT

878,583

adversarial cases · 0 leaks (nothing but ParamError escaped)

qint always returns a bounded int · qstr str-or-None · qflag bool. No user input can 500 the server.

WHY IT MATTERS

This is an OFFLINE search engine that takes arbitrary NSNs, part numbers and free text from mechanics. The param validator ensures a clean 400 message — never a stack-trace / 500. That's the 'above military grade' robustness bar applied to the input.

R1 · test-only; no product code touched. Guarded (skips if module absent). Runs host-side (VERIFY-099 smoke + RUN-HARDENING full). R9 sentinel intact.
