

FIX — why /api/threed_refs returned 500 (v0.72.2)

One red line in VERIFY-ALL. Plain version: a helper function moved to a new file, and one old caller never got the new address.

What actually happened, step by step

- 1 A test asked the 3D viewer: where does part 5305-01-674-1467 show up in the manuals?
- 2 That handler also lists which Smart Collections the part belongs to — so it calls a helper named `_collections_defs()`.
- 3 Back in v0.70 we split the big server file up; `_collections_defs()` MOVED into `collections_feature.py`.
- 4 The move re-imported the 5 public collection functions back — but NOT this one internal helper.
- 5 So at request time the server looked for `_collections_defs()`, couldn't find the name -> `NameError`.
- 6 The route wraps everything in catch-any-error -> return 500, so the user/test just saw HTTP 500.

THE FIX (one line)

Add the missing name to the import in `viewer_app.py`: `from collections_feature import (... , _collections_defs)`. Nothing else changed — no new logic, no database touch. The page-search half of the same handler was always fine because it had its own error guard; that's why only ONE of 86 checks was red.

Layman's analogy: a department (the helper) moved to a new building. Most callers got the new address; this one kept dialing the old room number and got 'no such extension' — which the switchboard reported as a generic 'error 500'.

Verified: reproduced the import + injected-core mechanism in isolation (both resolve); grepped for any OTHER helpers left behind by the split — none. Re-run `VERIFY-ALL.bat` to see `test_routes` go 34/34.
