

Tighter sorting — cache + overrides + corroboration (v0.74.0)

Built on the operator/mechanic split: higher accuracy, constant speed, RPS-safe. Index never written (R1/R6).

⚡ Side-map cache (speed)

- Classify every document ONCE.
- Keyed on doc-count + max id + override mtime.
- /api/by_side, counts, side-search reuse it.
- Rebuilds only when docs/overrides change -> O(1).

Faster, never slower.

📖 Manual overrides (accuracy)

- sides_override.json sidecar (append-only + log).
- Pin any doc: operator / mechanic / both.
- Overrides always win; POST /api/side_override.
- Review-uncertain panel = one-click pins.

Fix the tail, no guessing.

📄 Cover/MAC corroboration

- LOW-confidence docs only (no TM code).
- Reads OCR'd page 1 already in the index.
- 'OPERATOR'S MANUAL' -> operator;
- 'MAINTENANCE ALLOCATION CHART' -> mechanic.

Evidence, not defaults. No global cost.

confidence on every classification

tm_side() now returns high (from the coverage code) / medium (title or cover wording) / low (defaulted), and 'override' once pinned. The UI surfaces low+medium as 'uncertain' for review, and ?side= deep links open straight to a side; operator-side declutters the parts-request CTA (reversible).

VERIFIED

tm_side confidence 5/5. sides_feature end-to-end on a 6-doc fixture with OCR cover pages + an override: counts 3 operator / 4 mechanic / 1 both / 1 uncertain; cover->operator, MAC->mechanic, override flips the doc and the cache rebuilds. Route added to the host suite (RUN-ALL-TESTS.bat) — sandbox mount was stale at build time.

Phase-2 (planned, not built): chapter-level routing

A combined -12/-13/-14 has operator AND maintenance chapters on different pages. Using the OCR'd table of contents, drop each side into its own chapters of the book. Sidecar + cache + override, falls back to whole-book. See docs/SIDE-CHAPTER-ROUTING-PLAN.md — trigger after reviewing the real-corpus split.
