

Tighter part-number ↔ figure correlation (proposal)

Example: P/N 12420572-010 → HOSE, NONMETALLIC. Goal: key on the PART NUMBER and land on the exact item, with the right name.

Today

- Key = NSN only. Part number is not indexed.
- A part maps to its WHOLE figure (one crop).
- Stored nomenclature = the figure TITLE (noisy,
- not the part's real name).

Proposed

- Key = PART NUMBER (+ CAGEC) and item number.
- Parse the RPSTL parts-LIST table into rows.
- Real nomenclature, validated against FLIS.
- Land on the exact item — and its callout.

The RPSTL parts list already carries the mapping — we just need to parse its columns

ITEM	SMR	NSN	CAGEC	PART NUMBER	NOMENCLATURE	QTY
7	PAOZZ	4720-01-...	19207	12420572-010	HOSE, NONMETALLIC	2

Each row ties: part number → item # (the balloon in the figure) → NSN → SMR → the real nomenclature. CAGEC disambiguates same-number parts from different makers.

The correlation chain we'd build

Why this is accurate, legal, offline

It reads the manual's OWN parts list (OCR text we already have) and validates names/NSNs against PUB LOG/FLIS (already on disk). No external CAD, no guessing. Sidecar + confidence-scored + review/override like the sides feature; the 3.65 GB index is never written (R1/R6). Caveat: OCR table rows can drift — handled with multi-signal column detection + a confidence score + a human review queue.
